the desire to expose the spine for surgery by anterior approaches at any level between the head and the sacrum is not new spinal pathology is often located anterior to the spinal cord and nerve roots in the cervical and thoracic spine and anterior to the peripheral nerves that emerge from the lumbosacral spine below the first lumbar vertebra to treat such pathology one prefers to expose the front of the spine directly and widely enough to eradicate the pathology and to have full control of bleeding throughout the procedure the posterior elements of the spine are important for mechanical stability of the spine and therefore for the protection of the neural and vascular structures in the spine that would be threatened by instability

extensive eradication of pathology posterior to the spinal canal and the intervertebral foraminae including the transverse processes may leave no adequate bony bed for the surgical creation of a stabilizing osseous fusion in such a situation an anterior fusion procedure is the only viable alternative to a posterior or posterolateral fusion in situations where it is critically important to obtain a stable fusion as in tuberculosis of the spine both an anterior and a posterior fusion operation at the same motion segments is in almost every instance a guarantee of a stable osseous fusion one should know both approaches
