the standard multiple use calibration procedure due to scheffe 1973 states that with probability 1 delta the proportion of calculated confidence intervals containing the true unknowns is at least 1 alpha in the long run the probability 1 delta refers to the probability that the calibration experiment results in a good outcome in scheffe s formulation a good outcome involves both coverage of the true underlying regression curve and an upper confidence limit for sigma the scale parameter scheffe s procedure is fairly difficult for practitioners to apply because it relies on tables that are not easy to use a simpler notion of goodness which only requires the calibration experiment to result in coverage of the underlying regression leads to easily calculated confidence intervals for the unknowns in addition these intervals are generally shorter than scheffe s an application example is given to illustrate the technique keywords scheffe uncertainty bounds confidence intervals nonparametric calibration calibration curves mjm
